An introduction to GAM(M)s

Stefano Coretta

12/07/2018

Practical info

- All materials available at https://github.com/stefanocoretta/gamm-workshop
- Useful resources:
 - Generalised additive mixed models for dynamic analysis in linguistics:
 a practical introduction, Márton Sóskuthy
 [https://arxiv.org/abs/1703.05339]
 - Generalized additive modeling to analyze dynamic phonetic data: a tutorial focusing on articulatory differences between L1 and L2 speakers of English, Martijn Wieling [https://doi.org/10.1016/j.wocn.2018.03.002]
 - How to analyze linguistic change using mixed models, Growth Curve Analysis and Generalized Additive Modeling, Bodo Winter and Martijn Wieling [https://doi.org/10.1093/jole/lzv003]

Outline

Part 1

- ► Linear models
- ► Introduction to GAM theory
- Comparing groups
- ► Significance testing

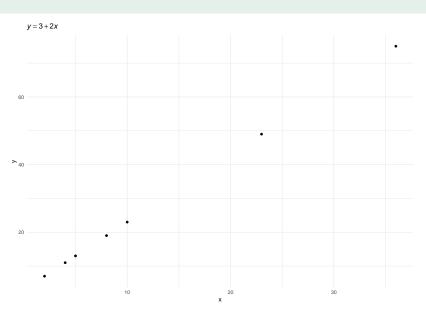

Part 2

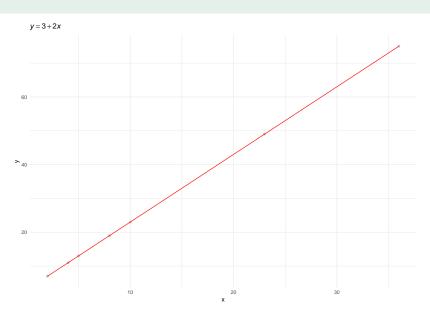

- Dynamic data
- ► Random effects
- Interactions

Time travel...

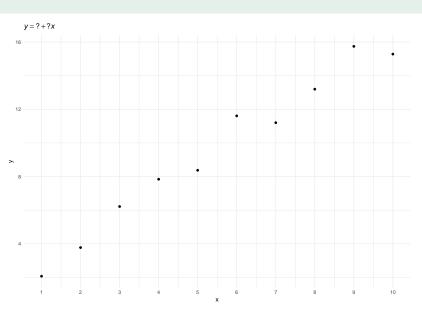

$$y = 3 + 2x$$

where $x = (2, 4, 5, 8, 10, 23, 36)$

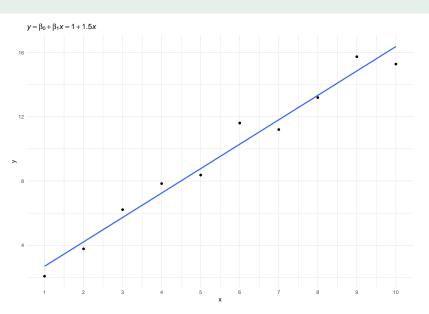

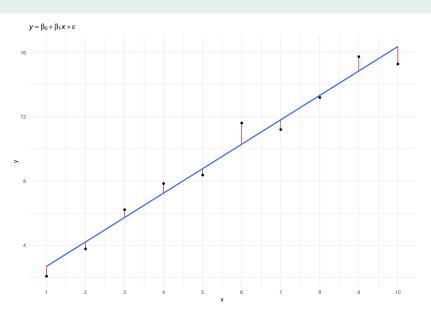

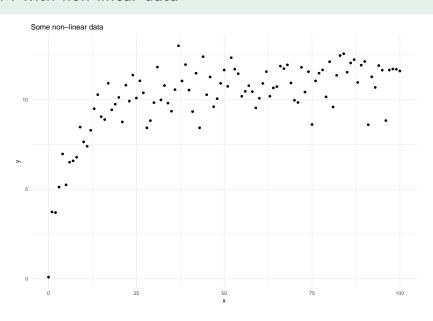

- ► In science, we have x and y...
- ▶ for example, vowel duration and VOT, speech rate and pitch, etc...

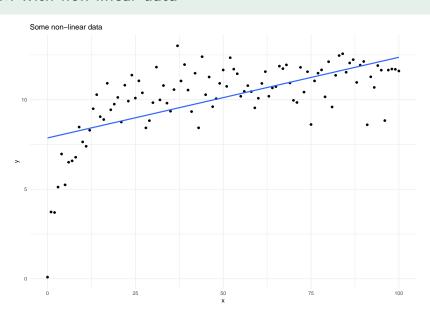

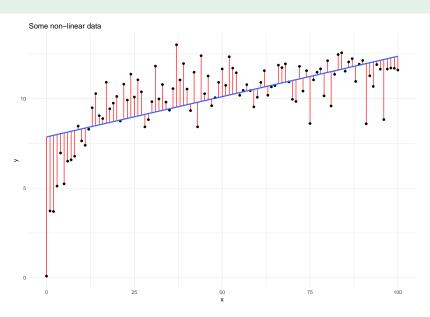

- ▶ The formula: $y = \beta_0 + \beta_1 x$
 - \triangleright β_0 is the **intercept**
 - \triangleright β_1 is the **slope**
- ▶ We know x and y
 - we need to estimate β_0 , $\beta_1 = \hat{\beta}_0$, $\hat{\beta}_1$
- ► We can add more predictors
 - $y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + ... + \beta_n x_n$
- ▶ $lm(y \sim x, data)$ ('y as a function of x')

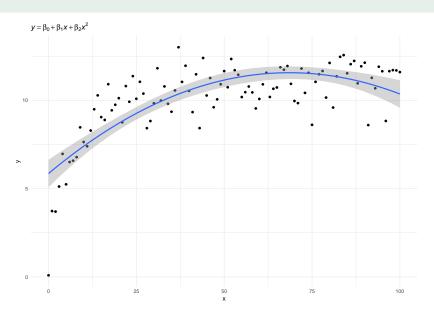

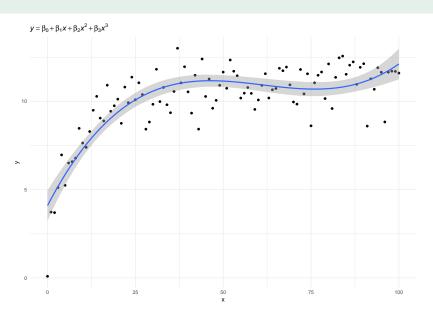

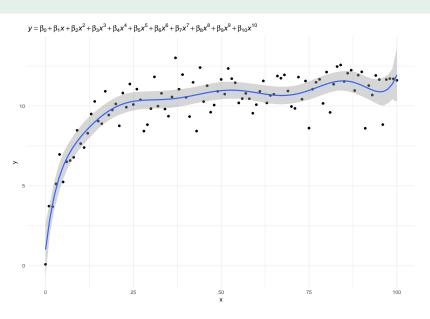

How to account for non-linearity in a linear model?

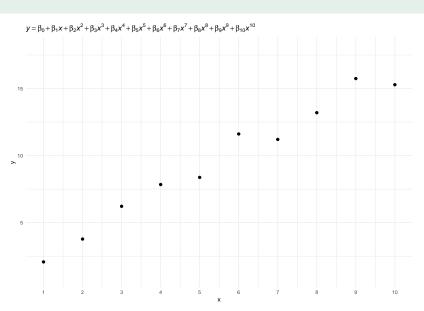

Use higher-degree polynomials

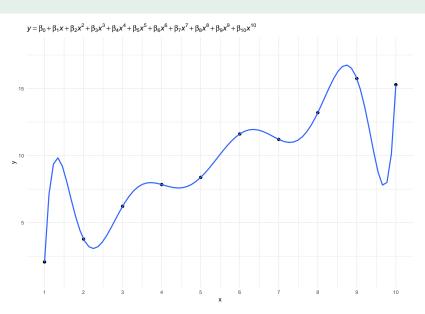

- quadratic: $y = \beta_0 + \beta_1 x + \beta_2 x^2$
- cubic: $y = \beta_0 + \beta_1 x + \beta_2 x^2 + \beta_3 x^3$
- *n*th: $y = \beta_0 + \beta_1 x + \beta_2 x^2 + \beta_3 x^3 + ... + \beta_n x^n$

Generalised additive models

- ► Genrealised Additive Models
- $y = f(x) + \epsilon$
 - f(x) = 'some function of x' (or smooth function)

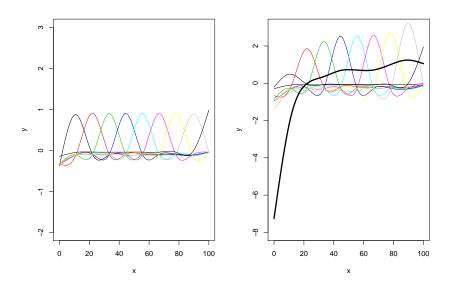

Smooth terms

- ► LMs have parametric terms
 - $\triangleright \beta_n x_n$
 - x in R
 - ► linear effects
- ► GAMs add (non-parametric) **smooth terms** (or simply smooths, also smoothers)
 - ► f(x)
 - s(x) in R
 - non-linear effects
- ▶ library(mgcv); gam(y ~ s(x), data), 'y as some function of x'

Smoothing splines, basis, basis functions

- ► Smooths in GAMs are **smoothing splines**
 - splines are defined piecewise with a set of polynomials
- ► The set of polynomials is called a basis
 - the basis is composed of basis functions (the polynomials)
- A spline is the sum of the products of each basis function and its coefficient

Basis functions and knots

Smoothing parameter

- 'Wiggliness' is related to number of basis functions
 - more basis functions, more wiggliness (less smoothing)
- ► The **smoothing parameter** penalises wiggliness
 - high values = less wiggliness (more smoothing)
 - estimated from the data

Smoothing splines

- ► There are **several kinds** of splines
 - each with their own basis functions
- Most common
 - thin plate regression splines
 - cubic regression splines
- ► For more info, run ?smooth.terms

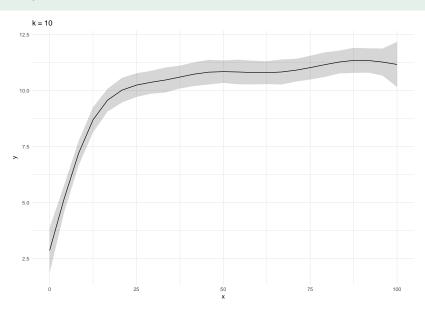

A simple GAM

```
simple <- gam(
    y ~
       s(x, bs = "cr", k = 10),
    data = sim_nl_a
)</pre>
```

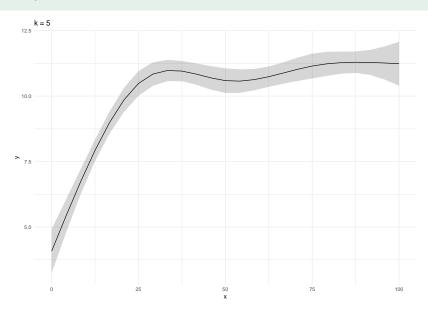

A simple GAM

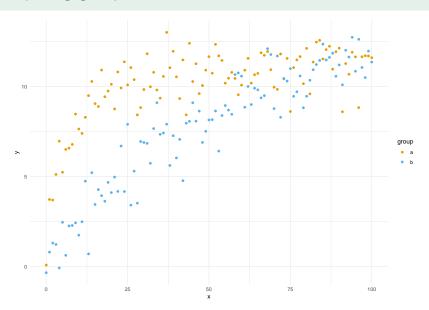

```
summary(simple)
##
## Family: gaussian
## Link function: identity

A simple GAM

A simple GAM:

by-variables with ordered factors

```
compare <- gam(
    y ~
        group +
        s(x, bs = "cr", k = 5) +
        s(x, bs = "cr", k = 5, by = group),
    data = sim_nl
)</pre>
```

- ► To use by-variables with ordered factors
 - change factor to ordered factor
 - change factor contrast to treatment contrast (contr.treatment)
 - the default in ordered factors is contr.poly, this won't work
 - include factor as parametric term
 - include a reference smooth and a difference smooth with the by-variable

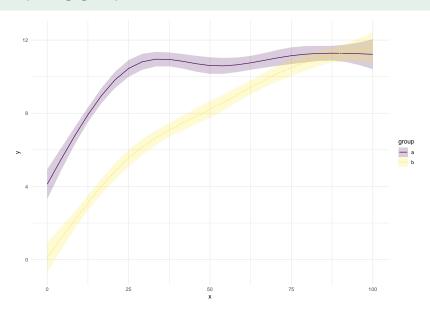

```
sim_nl <- sim_nl %>%
  mutate(group = ordered(group, levels = c("a", "b")))
contrasts(sim_nl$group) <- "contr.treatment"</pre>
```

```
compare <- gam(</pre>
    # parametric term
    group +
    # reference smooth
    s(x, bs = "cr", k = 5) +
    # difference smooth
    s(x, bs = "cr", k = 5, by = group),
  data = sim_nl
```

```
##
## Family: gaussian

```

```
library(tidymv)

plot_smooths(
  model = compare,
  time_series = x,
  comparison = group
)
```

- Several ways for testing significance of smooths
- We will used a combined method
 - model comparison with itsadug::compareML() of a full and a null model
 - visualisation of the difference smooth with

```
tidymv::plot_difference()
```

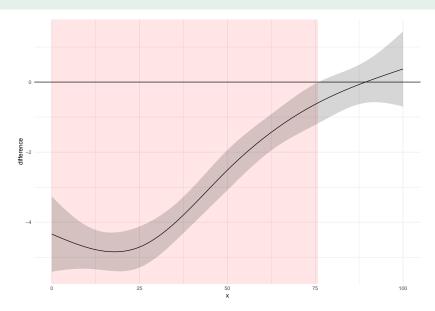

- (you can also use itsadug::plot_diff())
- Caveats
 - models need to be fitted with method = "ML"
 - can test either fixed or random effects, not both at the same time

```
group_full <- gam(</pre>
   group +
    s(x, bs = "cr", k = 5) +
    s(x, bs = "cr", k = 5, by = group),
  data = sim_nl,
  method = "ML"
group_null <- gam(</pre>
    s(x, bs = "cr", k = 5),
  data = sim_nl,
  method = "ML"
```

```
compareML(group_null, group_full)
## group null: v \sim s(x, bs = "cr", k = 5)
##
## group_full: y \sim \text{group} + s(x, bs = "cr", k = 5) + s(x, bs = "cr", k = 5, by = "cr", k = 5)
##
## Chi-square test of ML scores
## ----
          Model Score Edf Difference Df p.value Sig.
##
## 1 group_null 422.4827 3
## 2 group_full 314.0105 6 108.472 3.000 < 2e-16 ***
##
## AIC difference: 221.22, model group_full has lower AIC.
```

▶ Let's plot the difference smooth with tidymv::plot_difference()

```
plot_difference(
  model = group_full,
  time_series = x,
  comparison = list(group = c("b", "a"))
)
```

Hands on

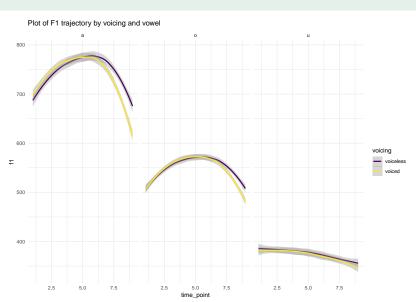

Practical 1

- "Dynamic speech analysis is a term used to refer to analyses that look at measureable quantities of speech that vary in space and/or time" (Sóskuthy, 2017)
- Examples
 - formant trajectories
 - pitch contours
 - geographic (diatopic) variation
 - tongue contours

- ► Two main types
 - time series data
 - spatial data
- ► More data (*n* > 1000)
 - use bam() (big GAM) instead of gam()

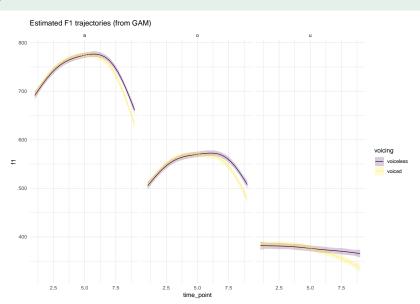

► formant trajectories (time series data)

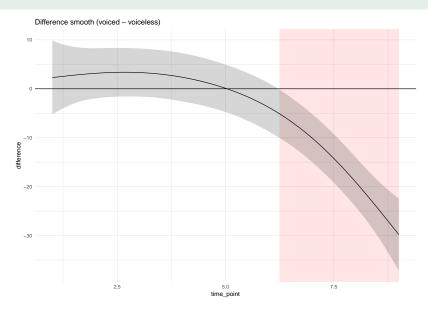

```
